4 July 28, 2025 4

5 **Abstract** 5

6 Economic connectivity, defined as the share of high-SES connections in one's network, 6  
7 is a strong correlate of labor market income. Yet, low-SES individuals are typically at 7  
8 a disadvantage when it comes to knowing the right people. Referral hiring leverages 8  
9 networks and make explicit the role of economic connectivity where taste-based biases 9  
10 could further exacerbate low-SES outcomes. We conduct a field experiment with 734 10  
11 university students to study the network compositions of different SES groups. We 11  
12 leverage enrollment networks to identify all potential referral candidates and conduct 12  
13 an incentivized referral exercise to reveal SES biases within these choice sets. We find 13  
14 that the university enrollment networks are highly segregated, with low-SES and high- 14  
15 SES individuals having a higher share of same-SES connections in their networks due 15  
16 to program selection (12% and 31% respectively). When considering ex post actualized 16  
17 choice sets for the observed referrals, the segregation becomes worse: Low-SES individu- 17  
18 als connect with other low-SES individuals at rates 30% higher than the university share, 18  
19 while high-SES individuals connect with other high-SES individuals at rates 55% higher 19

20 than the university share. Yet, we find no bias against low-SES individuals once we 20  
21 account for network structures. We randomly assign half of the participants to a condi- 21  
22 tion where their referral candidate receives a fixed bonus on top of pay-for-performance 22  
23 referral incentives. We find that additional incentives for the referral candidate do not 23  
24 change social proximity with the referral nor the referral quality. Our findings suggest 24  
25 that systematic segregation patterns in networks that alter choice sets matter more than 25  
26 taste-based SES biases in referrals, and highlight the potential for institutional action 26  
27 in promoting SES diversity. 27

30 experiment 30

31    **1 Introduction**

31

32    Equally qualified individuals in terms of productivity face different labor market out- 32  
33    comes based on their socioeconomic status (Stansbury & Rodriguez, 2024). This per- 33  
34    sistent inequality undermines meritocratic ideals and represents a substantial barrier to 34  
35    economic mobility. A key driver of SES-based inequality in the labor market stems from 35  
36    differences in social capital.<sup>1</sup> Economic connectivity, defined as the share of high-SES 36  
37    connections among low-SES individuals, is the most important facet of social capital 37  
38    because it correlates strongly with labor market income (Chetty et al., 2022b). In this 38  
39    sense, a lack of social capital means lack of access to individuals with influential (higher 39  
40    paid) jobs and job opportunities. It implies having worse outcomes when using one's 40  
41    network to find jobs conditional on the capacity to leverage one's social network.<sup>2</sup> 41

42    Referral hiring—the formal or informal process where firms ask workers to recom- 42  
43    mend qualified candidates for job opportunities—is a common labor market practice 43  
44    that makes differences in social capital evident.<sup>3</sup> Since referrals originate from the net- 44  
45    works of referrers, the composition of referrer networks becomes a crucial channel that 45  
46    propagates inequality. Similar individuals across socio-demographic characteristics form 46  
47    connections at higher rates (McPherson et al., 2001), making across-SES (low-to-high) 47  
48    connections less likely than same-SES connections (Chetty et al., 2022b). Referrals will 48  
49    thus reflect similarities in socio-demographic characteristics present in networks even in 49  
50    the absence of biases in the referral procedure—that is, even when referring randomly 50  
51    from one's network according to some productivity criteria. 51

52    Yet, experimental evidence shows referrals can be biased even under substantial 52

---

<sup>1</sup>See for example Bourdieu (1986); Loury (1977) for pioneering work on the relationship between social position and human capital acquisition.

<sup>2</sup>See for example Lin et al. (1981); Mouw (2003) for differential outcomes while using contacts in job search, and Pedulla and Pager (2019); Smith (2005) specifically for the effects of race conditional on network use.

<sup>3</sup>Referrals solve some frictions in the search and matching process and benefit both job-seekers and employers. As a consequence, referral candidates get hired more often, have lower turnover, and earn higher wages (Brown et al., 2016; Dustmann et al., 2016; Friebel et al., 2023).

53 pay-for-performance incentives beyond what is attributable to differences in network 53  
54 compositions, at least in the case of gender (Beaman et al., 2018; Hederos et al., 2025). 54  
55 A similar bias against low-SES individuals may further exacerbate their outcomes. If 55  
56 job information is in the hands of a select few high-SES individuals to whom low-SES 56  
57 individuals already have limited network access due to their lack of economic connec- 57  
58 tivity, and high-SES referrers are biased against low-SES individuals—referring other 58  
59 high-SES individuals at higher rates than their network composition would suggest—we 59  
60 should expect referral hiring to further disadvantage low-SES individuals. 60

61 The empirical question we answer in this paper is whether referrers exhibit bias 61  
62 against low-SES peers after accounting for differences in network SES composition. We 62  
63 also evaluate the causal impact of two different incentive structures on referral behavior. 63

64 In this study, we examine inequalities related to SES by curating a university-wide 64  
65 network dataset comprising over 4,500 students for whom classroom interactions are 65  
66 recorded along with individual attributes. We focus on the role of SES in referrals 66  
67 by experimentally investigating whether individuals who are asked to refer a peer tend 67  
68 to refer a same-SES candidate. We also explore potential mechanisms behind referral 68  
69 patterns by randomizing participants into two different incentive structures. To this end, 69  
70 we conducted a lab-in-the-field experiment with 734 students at a Colombian university. 70  
71 We instructed participants to refer a qualified student for tasks similar to the math and 71  
72 reading parts of the national university entry exam (equivalent to the SAT in the US 72  
73 system). To incentivize participants to refer qualified candidates during the experiment, 73  
74 we set earnings to depend on referred candidates' actual university entry exam scores. 74

75 Referral hiring in the labor market can range from firm-level formal referral programs 75  
76 asking employees to bring candidates to simply passing on job opportunities between 76  
77 network members (Topa, 2019). Since our participants are students at the university 77  
78 and refer based on exam scores, we abstract away from formal referral programs with 78  
79 defined job openings. Our setting instead resembles situations where contacts share 79  
80 opportunities with each other without requiring the referred candidate to take any action 80  
81 and without revealing the referrer's identity. This eliminates reputational concerns since 81

82 there is no hiring employer. It also establishes a lower bound on the expected reciprocity 82  
83 for the referrer when combined with pay-for-performance incentives (Bandiera et al., 83  
84 2009; Witte, 2021). At the same time, referring based on university entry exam scores 84  
85 is still an objective, widely accepted measure of ability. We show evidence that referrers 85  
86 in our setting not only possess accurate information about these signals but can also 86  
87 screen more productive individuals from their university network. 87

88 In a university setting, class attendance provides essential opportunities for face- 88  
89 to-face interaction between students. This is a powerful force that reduces network 89  
90 segregation by providing ample opportunities to meet across SES groups, because of 90  
91 exposure to an equal or higher level of high-SES individuals compared to the general 91  
92 population (Chetty et al., 2022a).<sup>4</sup> The very high level of income inequality in Colombia 92  
93 makes SES differences extremely visible in access to tertiary education, where rich and 93  
94 poor typically select into different institutions (Jaramillo-Echeverri & Álvarez, 2023). 94  
95 However, in the particular institutional setting we have chosen for this study, different 95  
96 SES groups mix at this university, allowing us to focus on SES diversity within the 96  
97 institution. At the same time, as students take more classes together, their similarities 97  
98 across all observable characteristics tend to increase (Kossinets & Watts, 2009). This 98  
99 is an opposite force that drives high- and low-SES networks to segregate. We observe 99  
100 the net effect of these two opposing forces using administrative data and construct class 100  
101 attendance (enrollment) networks for 734 participants based on the number of common 101  
102 courses they have taken together with other students. This allows us to directly identify 102  
103 aggregate characterizations of different SES groups' network compositions as a function 103  
104 of courses taken (e.g., in same-SES share), as well as the individual characteristics of 104  
105 network members who receive referrals among all possible candidates. 105

106 We find strong evidence that networks of high- and low-SES participants exhibit 106  
107 same-SES bias. On average, both groups connect with their own SES group at higher 107

---

<sup>4</sup>In a different sample from the same university population, Díaz et al. (2025) show this holds true for the highest-SES individuals at this institution, accounting for about 6% of their sample but less than 5% of Colombian high-school graduates (Fergusson & Flórez, 2021a).

108 rates than would occur randomly given actual group shares at the university (12% for 108  
109 low-SES and 31% for high-SES). As students take more courses together within the 109  
110 same program, their networks dwindle in size and become even more homogeneous in 110  
111 SES shares. At 12 courses together (the median number of courses taken together among 111  
112 referrals), the same-SES share increases to 30% above the university share for low-SES 112  
113 students and 55% above for high-SES students. We identify selection into academic 113  
114 programs as a key mechanism explaining this phenomenon: The private university where 114  
115 our study took place implements exogenous cost-based program pricing and does not offer 115  
116 SES-based price reductions. This results in programs with very large cost differences 116  
117 within the same university, with some programs costing up to six times the cheapest 117  
118 one. We find that the average yearly fee paid per student increases with SES, and the 118  
119 high-SES share in the most expensive program at the university—medicine—drives a 119  
120 large part of the network segregation across SES groups. 120

121 Do segregated networks account for the differences in SES referral rates across SES 121  
122 groups? Same-SES referrals are 17% more common than referrer networks suggest. 122  
123 Controlling for differences in network compositions, we find that the entirety of the bias 123  
124 is driven by low-SES referrers. We find no bias against low-SES peers beyond what is 124  
125 attributable to differences in network composition. Regardless of SES, participants refer 125  
126 productive individuals, and referred candidates are characterized by a very high number 126  
127 of courses taken together. The latter underlies the impact of program selection on the 127  
128 intensity of social interaction, where participants activate smaller and more homogeneous 128  
129 parts of their networks for making referrals. Our treatment randomized participants 129  
130 across two different incentive schemes by adding a substantial monetary bonus (\$25) 130  
131 for the referred candidate on top of the pay-for-performance incentives. We provide 131  
132 evidence that treatment incentives did not change referral behavior across the same-SES 132  
133 referral rate, the number of courses taken together with the referral candidate, and the 133  
134 candidate's exam scores. We interpret the lack of differences in the number of courses 134  
135 taken together as further evidence that referrals go to strong social ties across both 135

136 treatments regardless of the incentive structure.<sup>5</sup> 136

137 Our main empirical contribution to the experimental referral literature is our obser- 137  
138 vation of the entire network that characterizes the referral choice set. Earlier research 138  
139 compares referrals made across different incentive structures and makes inferences about 139  
140 the counterfactual. For example, [Beaman and Magruder \(2012\)](#) compared referrers paid 140  
141 based on their referred candidate's productivity instead of receiving a fixed finder's fee, 141  
142 and [Beaman et al. \(2018\)](#) compared referrers who were restricted to refer either a male 142  
143 or female candidate instead of choosing freely. While [Pallais and Sands \(2016\)](#) recruited 143  
144 a random sample of non-referred workers for comparison with referred ones, none of 144  
145 the previous studies could identify the entire referral choice set and provide a direct 145  
146 comparison to those who were referred by the participants. Observing the entire net- 146  
147 work allows us to identify biases in referrals in a more natural way, without imposing 147  
148 restrictions on the choice sets. A similar approach to ours is [Hederos et al. \(2025\)](#), who 148  
149 elicited friendship networks by asking referrers to name 5 close friends. Their findings 149  
150 suggest only half of those who were referred were from the elicited friendship network, 150  
151 and thus represent an incomplete observation of the entire referral choice set. We take 151  
152 our analysis one step further by requesting referrals from the enrollment network, where 152  
153 we have complete information on every single connection that may or may not receive 153  
154 a referral. This allows us to neatly separate the effect of network composition from any 154  
155 potential biases stemming from the referral procedure itself. 155

156 Second, we build upon the earlier work on inequalities in referrals and the role of SES 156  
157 differences. The reliance of labor markets on referrals, coupled with homophily in social 157  
158 networks, can lead to persistent inequalities in wages and employment ([Bolte et al., 2021](#); 158  
159 [Calvo-Armengol & Jackson, 2004](#); [Montgomery, 1991](#)). The premise of these models is 159  
160 that referrals exhibit homophily, so that employees are more likely to refer workers of 160  
161 their own race, gender, SES, etc. Supporting evidence shows that low-SES individuals 161  
162 have networks with lower shares of high-SES individuals, which partly explains why they 162

---

<sup>5</sup>This follows directly from earlier evidence showing that referrals tend to go to strong ties, i.e., close friends and/or family members ([Gee et al., 2017](#); [Kramarz & Nordström Skans, 2014](#); [Wang, 2013](#)).

163 have worse labor market outcomes (Chetty et al., 2022b; Stansbury & Rodriguez, 2024). 163  
164 We contribute by separately identifying the role of network homophily (the tendency 164  
165 to connect with similar others) and referral homophily (the tendency to refer similar 165  
166 others). Our results suggest that network homophily, rather than referral homophily, 166  
167 drives SES inequality in our setting. 167

168 To our knowledge, Díaz et al. (2025) are the first to study SES biases in referrals, 168  
169 and our study is conceptually the closest to theirs. Drawing from a similar sample at 169  
170 the same institution, Díaz et al. (2025) focus on referrals from first-year students made 170  
171 within mixed-program classrooms and find no evidence for an aggregate bias against low- 171  
172 SES individuals. We also find no aggregate bias against low-SES individuals in referrals 172  
173 beyond what is attributable to differences in network structure. Our setup differs as we 173  
174 sample from students who completed their first year and impose no limits on referring 174  
175 from a classroom. This has several implications: We find that referrals in our setup go to 175  
176 individuals within the same program, and that programs have different SES shares which 176  
177 become even more accentuated as students take more courses together. While networks 177  
178 drive inequality in referral outcomes because of the institutional environment in our 178  
179 sample, we have no reason to believe first-year student networks in Díaz et al. (2025) 179  
180 have similar levels of segregation to begin with. Our findings suggest that implementing 180  
181 more mixed-program courses that allow for across-SES mixing should be a clear policy 181  
182 goal to reduce segregation (Alan et al., 2023; Rohrer et al., 2021). 182

183 The remainder of the paper is organized as follows. Section 2 begins with the back- 183  
184 ground and setting in Colombia. In Section 3 we present the design of the experiment. 184  
185 In Section 4 we describe the data and procedures. Section 5 discusses the results of 185  
186 the experiment and Section 6 introduces robustness checks. Section 7 concludes. The 186  
187 Appendix presents additional tables and figures as well as the experiment instructions. 187

## <sup>188</sup> 2 Background and Setting

<sup>188</sup>

<sup>189</sup> Our experiment took place in Colombia, a country that consistently ranks among the <sup>189</sup>  
<sup>190</sup> most unequal in Latin America. The richest decile of Colombians earn 50 times more <sup>190</sup>  
<sup>191</sup> than the poorest decile ([United Nations, 2023](#); [World Bank, 2024](#)). This economic dis- <sup>191</sup>  
<sup>192</sup> parity creates profound differences in outcomes across SES groups in terms of education, <sup>192</sup>  
<sup>193</sup> geographic residence, language, manners, and social networks ([Angulo et al., 2012](#); <sup>193</sup>  
<sup>194</sup> [Fergusson & Flórez, 2021b](#); [García et al., 2015](#)). While these patterns are not atypical and <sup>194</sup>  
<sup>195</sup> exist elsewhere ([Chetty et al., 2022b](#)), Colombia's pronounced inequality makes class- <sup>195</sup>  
<sup>196</sup> based differences particularly visible. This combination of economic, educational, and <sup>196</sup>  
<sup>197</sup> cultural segregation provides an ideal setting to study SES biases in referral selection. <sup>197</sup>

<sup>198</sup> We rely on Colombia's established estrato classification system to operationalize <sup>198</sup>  
<sup>199</sup> SES in our study. In 1994, Colombia introduced a nationwide system that divides the <sup>199</sup>  
<sup>200</sup> population into six strata based on "similar social and economic characteristics" ([Hudson](#) <sup>200</sup>  
<sup>201</sup> & [Library of Congress, 2010](#), p. 102). Designed for utility subsidies from higher strata to <sup>201</sup>  
<sup>202</sup> support lower strata, the system aligns with and reinforces existing social class divisions <sup>202</sup>  
<sup>203</sup> ([Guevara S & Shields, 2019](#); [Uribe-Mallarino, 2008](#)). It is widely used by policymakers <sup>203</sup>  
<sup>204</sup> and in official statistics ([Fergusson & Flórez, 2021a](#)). Using the estrato system, we <sup>204</sup>  
<sup>205</sup> categorize students in strata 1-2 as low-SES, strata 3-4 as middle-SES, and strata 5- <sup>205</sup>  
<sup>206</sup> 6 as high-SES. The institutional recognition and widespread use of this system makes <sup>206</sup>  
<sup>207</sup> Colombia methodologically advantageous for studying SES-based phenomena. <sup>207</sup>

<sup>208</sup> Colombia's educational segregation typically prevents meaningful interaction be- <sup>208</sup>  
<sup>209</sup> tween socioeconomic groups, as wealthy families attending exclusive private schools while <sup>209</sup>  
<sup>210</sup> poorer families access lower-quality public or private institutions ([Fergusson & Flórez,](#) <sup>210</sup>  
<sup>211</sup> [2021b](#)). However, non-elite private universities like our partner institution are outliers <sup>211</sup>  
<sup>212</sup> to this pattern. They attract students across the socioeconomic spectrum, unlike elite <sup>212</sup>  
<sup>213</sup> private institutions that serve primarily high-SES students or public universities that <sup>213</sup>  
<sup>214</sup> serve mainly low-SES students (see Figure 1).<sup>6</sup> Our study takes place at a medium- <sup>214</sup>

---

<sup>6</sup>Despite significant financial barriers, many low- and middle-SES families pay for private university education for their children ([Hudson & Library of Congress, 2010](#), p. 103).

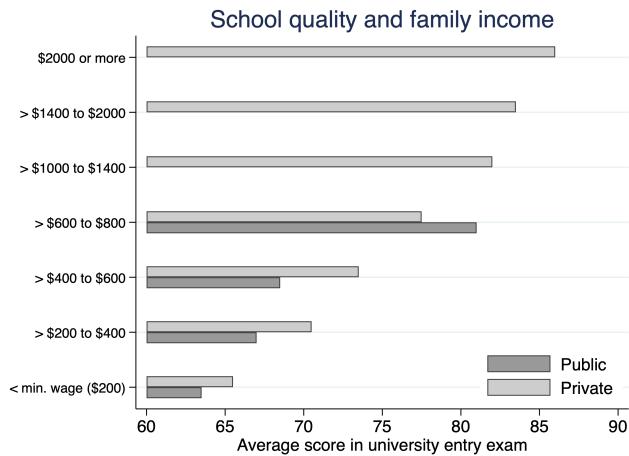

215 sized private university in Colombia with approximately 6,000 enrolled undergraduate 215  
216 students. Its student body is diverse, comprising approximately 35% low-SES, 50% 216  
217 middle-SES, and 15% high-SES students.<sup>7</sup> This diversity solves the fundamental prob- 217  
218 lem of providing opportunities for different SES groups to meet and interact within the 218  
219 same institutional framework. 219

220 decide what to do here: Beyond providing opportunities for meeting across SES 220  
221 groups (cross-SES contact), the partner university also creates conditions for contact on 221  
222 equal status. First, all students at the university pay the same fees based on their pro- 222  
223 gram choice, and typically less than 5% of students receive any scholarship. The student 223  
224 body is also relatively homogeneous along other demographic dimensions, being mostly 224  
225 urban and having similar university entry exam scores ADD NUMBERS. According 225  
226 to contact theory, meaningful interaction between groups is most likely to reduce bias 226  
227 when members have equal status within the contact situation (Allport, 1954; Pettigrew 227  
228 & Tropp, 2006). The combination of SES diversity and equal institutional status makes 228  
229 this setting particularly well-suited for identifying pure socioeconomic biases in referral 229  
230 behavior, as other potential sources of differentiation are minimized. 230

---

<sup>7</sup>In contrast, government statistics reveal less than 5% of the population is high-SES (Hudson & Library of Congress, 2010, p. 103).

Figure 1: Income, performance, and university choice in Colombia

*Note:* This figure shows the average score national university entry exam by monthly family income and type of higher education institution. With average student score in the 65-70 band, the private university where we conducted this experiment caters to low- and high-SES students. Figure reproduced from [Fergusson and Flórez \(2021b\)](#).

231 To operationalize SES in our study, we rely on Colombia's established classification 231  
 232 system. In 1994, Colombia introduced a nationwide system that divides the population 232  
 233 into 6 strata based on housing characteristics and neighborhood amenities.<sup>8</sup> We use 233  
 234 this classification as our measure of SES in the experiment. Students in strata 1 to 2 234  
 235 are categorized as low-SES, strata 3 to 4 as middle-SES, and those in strata 5 to 6 as 235  
 236 high-SES. 236

237 For our experiment, we invited via email all 4,417 UNAB undergraduate students 237  
 238 who had completed their first year at the university at the time of recruitment. The 837 238  
 239 students who joined (19%) vary in terms of their academic programs, SES, and progress 239  
 240 in their studies. This experimental setup provides a unique opportunity for collaborative 240  
 241 inter-class contact on equal status, whose positive effects on reducing discrimination are 241

---

<sup>8</sup>Initially designed for utility subsidies from higher strata (5 and 6) to support lower strata (1 to 3), it now extends to university fees and social program eligibility. Stratum 4 neither receives subsidies nor pays extra taxes. This stratification system largely aligns with and potentially reinforces existing social class divisions ([Guevara S & Shields, 2019; Uribe-Mallarino, 2008](#)).

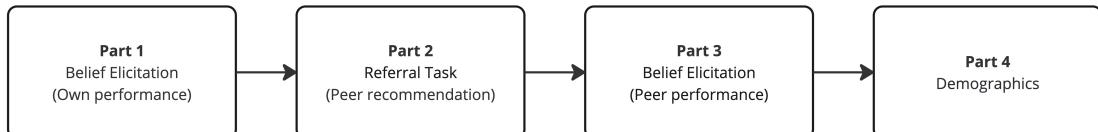

242 causally documented (Lowe, 2021; Mousa, 2020; Rao, 2019). 242

243 The institutional setup at UNAB sets up the social contact structure and facil- 243  
244 itates the network analysis. Undergraduate programs at UNAB are spread across two 244  
245 semesters, with each individual course lasting one semester. Students take between 5 to 245  
246 7 courses per semester, with programs lasting anywhere between 4 to 12 semesters (2 to 246  
247 6 years). Medicine, the largest program by size at UNAB, lasts for 12 semesters, followed 247  
248 by engineering programs at 10 semesters. Most remaining programs last for about 8 to 248  
249 10 semesters, with specialized programs for immediate entry into the workforce lasting 249  
250 only 4 semesters. 250

### 251 **3 Design** 251

252 We designed an experiment to assess peer referral behavior from an SES perspective and 252  
253 to causally evaluate the effect of different incentive structures on referrals. The study 253  
254 design consists of a single online experiment organized at the university level (see Figure 254  
255 2). The instructions are provided in Appendix B. 255

Figure 2: Experiment Timeline

*Note:* Participants first report beliefs about their own national university entry exam performance, then recommend peers for each academic area. In the final part, they report beliefs about their recommendations' performance and provide demographic information. This order is implemented for all participants.

#### 256 **3.1 Productivity measures** 256

257 To establish an objective basis for referral productivity, we use national university entry 257  
258 exam scores (SABER 11). These scores provide pre-existing, comparable measures of 258

ability across two domains relevant for the labor market. By using existing administrative data, we eliminate the need for additional testing and ensure that all eligible students have comparable productivity measures. The scores we use in this experiment consist of critical reading and mathematics parts.

Critical reading evaluates competencies necessary to understand, interpret, and evaluate texts found in everyday life and broad academic fields (e.g., history). This measures students' ability to comprehend and critically evaluate written material. Mathematics assesses students' competency in using undergraduate level mathematical tools (e.g., reasoning in proportions, financial literacy). This captures quantitative reasoning and problem-solving abilities.

For each area, we calculate percentile rankings based on the distribution of scores among all currently enrolled UNAB students, providing a standardized measure of relative performance within the university population.

### 3.2 Referral task

Building on these productivity measures, our main experimental task involves peer recommendations. After eliciting beliefs about their own performance, participants engage in incentivized peer recommendations. For both test areas (critical reading and mathematics), participants recommend one peer they believe excels in that domain. We first present an example question from the relevant test area to clarify what skills are being assessed. Participants then type the name of their recommended peer, with the system providing autocomplete suggestions from enrolled students who have taken the test (see Figure 3).

Figure 3: Referral task interface

**Your recommendation**

We are interested in your recommendation of the person you consider best to solve similar problems to those in the **Math test**.

- \* Only someone with whom you have taken at least one class...
- \* We will not contact your recommendation...

Please write the name of your recommendation:

John
John Lennon (Music - 2018) 
John Stuart Mill (Law - 2020)

*Note:* This illustration shows how the system provides suggestions from enrolled students with their program and year of study from the administrative database.

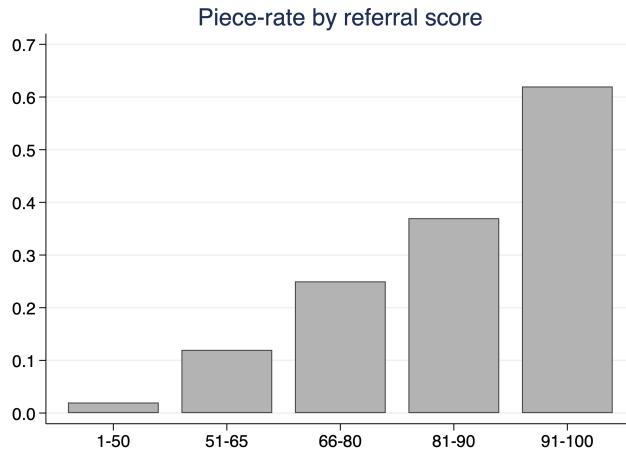

281 Participants can only recommend students with whom they have taken at least one 281  
282 class during their university studies. This requirement ensures that referrals are based on 282  
283 actual peer interactions and overlaps with the enrollment network that we construct. The 283  
284 order in which participants make recommendations across the two areas is randomized. 284

285 We incentivize referrals using a productivity-based payment scheme that rewards 285  
286 participants for recommending highly ranked peers. Referrers earn increasing monetary 286  
287 rewards as the percentile ranking of their recommendation increases (see Figure 4). This 287  
288 payment structure provides strong incentives to screen for highly ranked peers, with 288  
289 potential earnings up to \$60 per recommendation. We multiply the piece rate coefficient 289  
290 associated with the percentile rank by the actual test scores of the recommendation to 290  
291 calculate earnings.<sup>9</sup> 291

---

<sup>9</sup>Due to the selection into the university, the actual test score distribution has limited variance. Below a certain threshold students cannot qualify for the institution and choose a lower ranked university, and above a certain threshold they have better options to choose from.

Figure 4: Referral incentives

*Note:* This figure shows how the piece rate coefficient increases as a function of the referral ranking in the university, providing incrementally higher rewards for higher ranked peers.

292 3.3 Treatment variation

293 To examine how different incentive structures affect referral behavior, we implement a 293  
294 treatment that varies payment to recommended peers. We implement a between-subjects 294  
295 treatment that varies whether the recommended peer also receives payment. In the 295  
296 **Baseline** treatment, only the referrer can earn money based on their recommendation's 296  
297 productivity. The **Bonus** treatment adds an additional fixed payment of \$25 to any 297  
298 peer who is recommended in the randomly selected area for payment. This payment is 298  
299 independent of the peer's actual productivity (see Figure 1). 299

Table 1: Incentive structure by treatment

	<b>Baseline</b>	<b>Bonus</b>
Referrer (sender)	Productivity-based	Productivity-based
Recommendation (receiver)	No payment	Fixed reward

300 Participants are informed about their treatment condition before making recommendations 300

301 dations through both video and text instructions. The treatment is assigned at the 301  
302 individual level, allowing us to compare referral outcomes across conditions. 302

### 303 **3.4 Belief elicitation** 303

304 To understand participants' information and expectations, we collect incentivized beliefs 304  
305 at key points. We elicit incentivized beliefs at two points in the experiment. First, before 305  
306 making referrals, participants report their beliefs about their own percentile ranking in 306  
307 each test area. Second, after making each referral, participants report their beliefs about 307  
308 their recommendation's percentile ranking. For both belief elicitation tasks, participants 308  
309 earn \$5 if their guess is within 7 percentiles of the true value. This tolerance level is 309  
310 expected to balance precision with the difficulty of the task. 310

## 311 **4 Sample, Incentives, and Procedure** 311

312 We invited all 4,417 UNAB undergraduate students who had completed their first year 312  
313 at the university at the time of recruitment to participate in our experiment. A total 313  
314 of 837 students participated in the data collection, yielding a 19% response rate. Our 314  
315 final sample consists of 734 individuals who referred peers with whom they had taken at 315  
316 least one class together, resulting in an 88% success rate for the sample. We randomly 316  
317 allocated participants to either **Baseline** or **Bonus** treatments. 317

318 Table 2 presents key demographic characteristics and academic performance indi- 318  
319 cators across treatments (see Appendix Table A.1 for selection). The sample is well- 319  
320 balanced between the **Baseline** and **Bonus** conditions and we observe no statistically 320  
321 significant differences in any of the reported variables (all  $p$  values  $> 0.1$ ). Our sample is 321  
322 characterized by a majority of middle-SES students with about one-tenth of the sample 322  
323 being high-SES students. The test scores and GPA distributions are balanced. On av- 323  
324 erage, participants had taken 3.8 courses together with members of their network, and 324  
325 the average network consisted of 175 peers. 325

Table 2: Balance between treatments

	<b>Baseline</b>	<b>Bonus</b>	<i>p</i>
Reading score	64.712	65.693	0.134
Math score	67.366	67.597	0.780
GPA	4.003	4.021	0.445
Connections	173.40	176.88	0.574
Courses taken	3.939	3.719	0.443
Low-SES	0.419	0.401	0.615
Middle-SES	0.492	0.506	0.714
High-SES	0.089	0.094	0.824
Observations	382	352	734

*Note:* This table presents balance tests between **Baseline** and **Bonus** conditions. *p*-values for binary outcomes are from two-sample tests of proportions; for continuous variables, from two-sample *t*-tests with unequal variances. All reported *p*-values are two-tailed. Reading and math scores are in original scale units out of 100. GPA is grade point average out of 5. Connections refers to the average number of network members. Low-SES, Med-SES, and High-SES indicate SES categories based on strata.

326     The experiment was conducted online through Qualtrics, with participants recruited     326  
 327     from active UNAB students. To ensure data quality while managing costs, we randomly     327  
 328     selected one in ten participants for payment. Selected participants received a fixed     328  
 329     payment of \$17 for completion, plus potential earnings from one randomly selected     329  
 330     belief question (up to \$5) and one randomly selected recommendation question (up to     330  
 331     \$60). This structure resulted in maximum total earnings of \$82. The average time to     331  
 332     complete the survey was 30 minutes, with an average compensation of \$80 for the one in     332  
 333     ten participants randomly selected for payment. Payment processing occurred through     333  
 334     online banking platform Nequi within 15 business days of participation.     334

335 **5 Results**

335

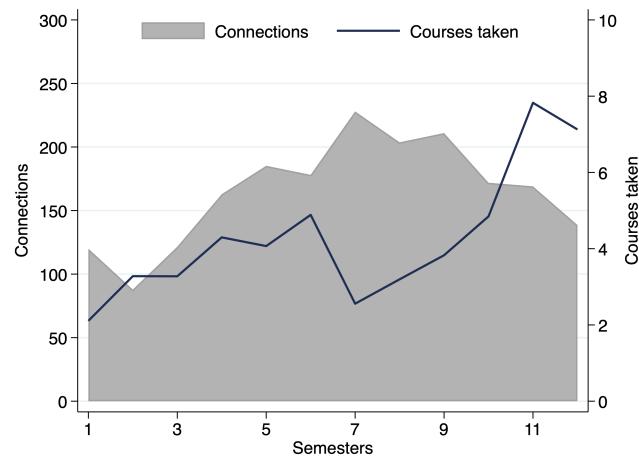

336 **5.1 Network characteristics**

336

337 We begin by describing the key features of the enrollment network for all participants. 337  
338 This network connects every participant in our sample with another university student 338  
339 if they have taken at least one course together at the time of data collection. By doing 339  
340 so, we construct the entire referral choice set for participants. We include in this dataset 340  
341 both the participant's and their potential candidate's individual characteristics, as well 341  
342 as the number of common courses they have taken together. Figure 5 describes the 342  
343 evolution of the enrollment network across the average number of network connections 343  
344 and the number of common courses taken with network members as participants progress 344  
345 through semesters.

345

Figure 5: Network size and courses taken together by time spent at  
the university

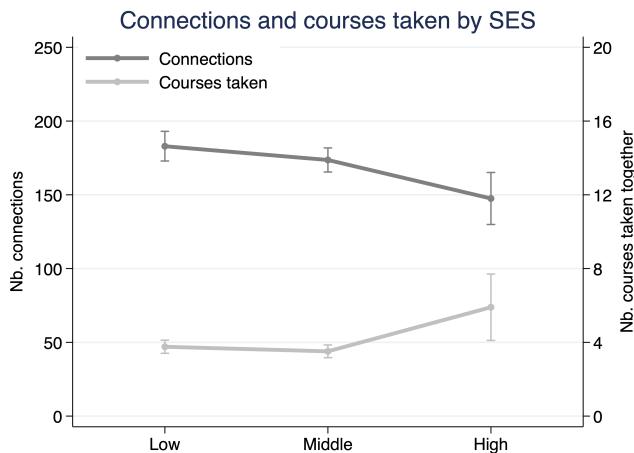

*Note:* This figure displays the average number of connections in blue and the average number of classes they have taken together with their connections in grey across semesters spent. The data shows an increase in the number of classes taken together as students progress in their programs, with the connections peaking around 7 semesters and dropping as certain students finish their bachelor's.

346 Having established the overall network structure, we now examine differences across 346

347 SES groups. Are enrollment networks different across SES groups? We look at how 347  
 348 the number of connections (network size) and number of courses taken together (tie 348  
 349 strength) change across SES groups in Figure 6. Low- and middle-SES students have 349  
 350 larger networks but take fewer courses together with network members, while high- 350  
 351 SES students have smaller, denser networks. Specifically, both low- and middle-SES 351  
 352 students have significantly larger networks than high-SES students ( $t = 3.03, p = .003$  352  
 353 and  $t = 2.49, p = .013$ , respectively), but high-SES students take significantly more 353  
 354 courses with their network members than both low- ( $t = -3.70, p < .001$ ) and middle- 354  
 355 SES ( $t = -4.20, p < .001$ ). 355

Figure 6: Network size and courses taken together by SES

Note: This figure displays the average number of connections and the average number of classes taken together across SES groups. The data shows a decrease in the number of connections with SES, and an associated increase in the number of classes taken together.

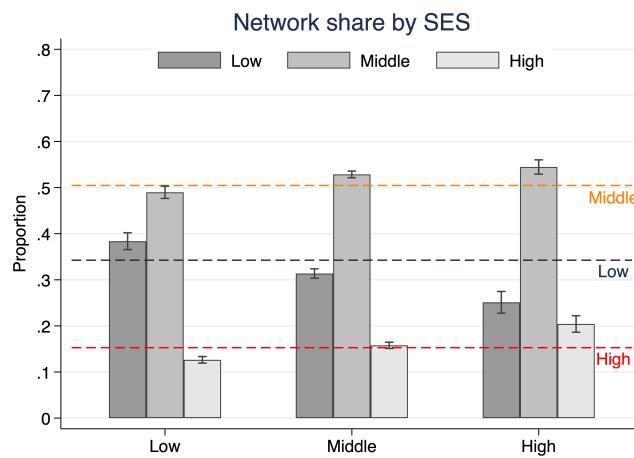

## 356 5.2 SES diversity in networks 356

357 What are the diversity-related consequences of SES-driven differences across networks? 357  
 358 In terms of network compositions, SES groups may connect with other SES groups 358  
 359 at different rates than would occur randomly (Figure 7).<sup>10</sup> Our results reveal mod-

<sup>10</sup>Because we estimate the share of SES groups in every individual network, we get very precise estimates of the actual means. However, it is important to note that these are not independent observations

360 est deviations from university-wide SES composition across groups. Low-SES students 360  
 361 have networks with 38.4% low-SES peers compared to the university average of 34.3%, 361  
 362 middle-SES students connect with 52.9% middle-SES peers versus the university aver- 362  
 363 age of 50.5%, and high-SES students show 20.4% high-SES connections compared to the 363  
 364 university average of 15.3%. 364

Figure 7: Network shares of SES groups

*Note:* This figure compares the network shares of SES groups in the networks of low-, middle-, and high-SES participants. Horizontal lines plot the university-wide shares of each SES group (Low: 35%, Mid: 51%, High: 14%). While the share of low-SES peers in the network decreases as the SES of the group increases, the share of high-SES peers in the network increases.

365 At the same time, we observe much larger differences between SES groups in their 365  
 366 connection patterns with other groups. Low-SES students connect with other low-SES 366  
 367 students at higher rates than middle-SES students (38.4% vs 31.4%) and high-SES stu- 367  
 368 dents (38.4% vs 25.1%). Conversely, high-SES students connect more with other high-

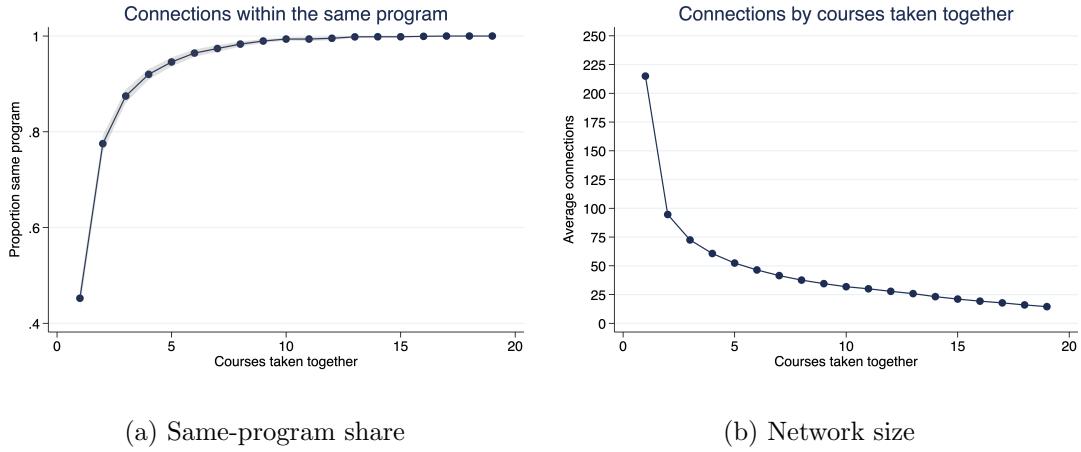

---

for each network. Estimates are precise because each network is a draw with replacement from the same pool of university population, from which we calculate the proportion of SES groups per individual network, and take the average over an SES group. Pooling over SES groups who are connected with similar others systematically reduces variance (similar to resampling in bootstrapping). For this reason we choose not reporting test results in certain sections including this one and focus on describing the relationships between SES groups.

369 SES students than both low-SES students (20.4% vs 12.6%) and middle-SES students 369  
370 (20.4% vs 15.8%). Middle-SES students are in between the two extreme patterns, con- 370  
371 necting with middle-SES peers at higher rates than low-SES students (52.9% vs 49.0%) 371  
372 but lower rates than high-SES students (52.9% vs 54.5%). These findings indicate SES- 372  
373 based network segregation, with same-SES homophily patterns across groups. 373

374 Having examined basic network composition, we now turn to connection intensity. So 374  
375 far we have looked at the entire network without considering the intensity of connections 375  
376 between students. In our network dataset, this variable amounts to the number of classes 376  
377 taken together with peers. As we will see in the next section, referrals go to peers with 377  
378 whom participants have taken an average of 14 courses, implying the intensity of the 378  
379 connection matters. We begin by dissecting what the intensity means in our context. 379  
380 As students take more courses together, the proportion of peers from the same academic 380  
381 program quickly goes beyond 95% (see Figure 8a). Similarly, the average network size 381  
382 drops very quickly from above 210 to below 50 (see Figure 8b). Both results indicate 382  
383 that actual referral considerations originate from a much smaller pool of individuals from 383  
384 the same academic program. 384

Figure 8: Network characteristics and courses taken together

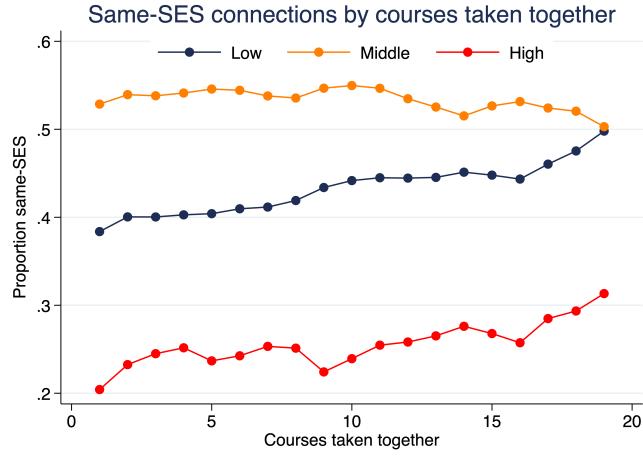

(a) Same-program share

(b) Network size

*Note:* The left panel illustrates the share of connections within the same program as a function of the number of courses taken together. The right panel shows the average network size as a function of the number of courses taken together. Taking more than 5 courses together with a network member means on average 90% chance to be in the same program. Similarly, past 5 courses together, the average network size dwindles by 80%, from more than 210 individuals to below 50.

385 This raises an important question: What are the diversity implications of increased 385  
 386 connection intensity between students? As students take more courses together with 386  
 387 peers, the share of same-SES peers in the networks of low- and high-SES increases 387  
 388 while the share of middle-SES declines (see Figure 9). Both increases are substantial, 388  
 389 amounting to 50% for high-, and 30% for low-SES. Combining these with the earlier 389  
 390 result that beyond 5 courses taken together network members are almost entirely within 390  
 391 the same program, these suggest program selection may have strong consequences for 391  
 392 SES diversity in our setting. 392

Figure 9: Network size and courses taken together by courses taken

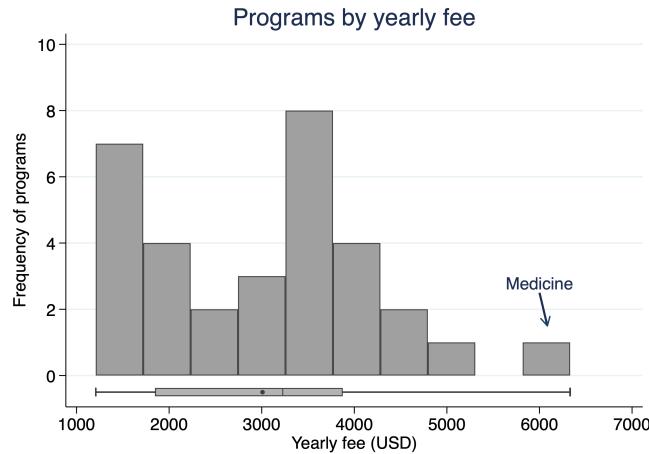

*Note:* This figure illustrates the shares of same-SES connections for low-, middle-, and high-SES as a function of the average number of courses taken together with network members. Low- and high-SES networks both become more homogenous as the average number of courses taken together with their connections increase.

### 393 5.3 Program selection and SES diversity

394 To understand the mechanisms driving these patterns, we examine program selection. 394  
 395 Academic programs at this university use cost-based pricing, and typically less than 5% 395  
 396 of students receive any kind of scholarship (Díaz et al., 2025). Based on this, we first 396  
 397 calculate how much every program at the university is expected to cost students per 397  
 398 year (see Figure 10). Considering that net minimum monthly wage stands at \$200 and 398  
 399 the average Colombian salary around \$350, the cost differences between programs are 399  
 400 large enough to make an impact on program selection. Is it the case that SES groups 400  
 401 select into programs with financial considerations? 401

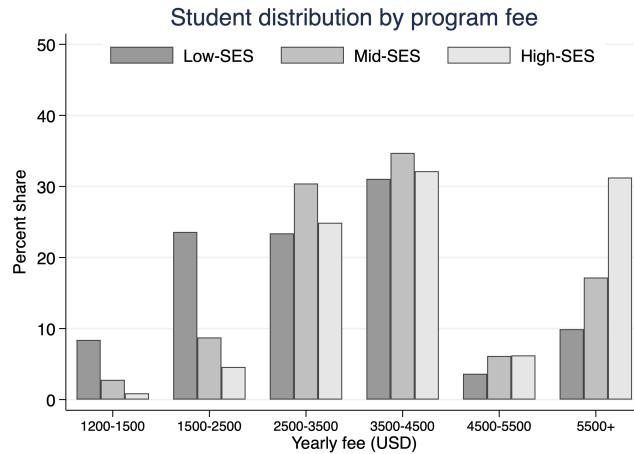

Figure 10: Programs sorted by fee

*Note:* This figure illustrates the distribution of programs at the university by their average yearly fee. The average yearly fee stands at \$3000, and medicine is an outlier at \$6000.

We examine how SES groups are distributed across programs to identify evidence of SES-based selection (see Figure 11). Indeed, low-SES students select into more affordable programs, followed by middle-SES students. High-SES students sort almost exclusively into above-average costing programs, with a third selecting into medicine and creating a very skewed distribution. The distributions are significantly different across all pairwise comparisons: low-SES vs. middle-SES (Kolmogorov-Smirnov test  $D = 33.89, p < 0.001$ ), low-SES vs. high-SES ( $D = 31.31, p < 0.001$ ), and middle-SES vs. high-SES ( $D = 31.31, p < 0.001$ ). With this finding, program selection could be the reason why low- and high-SES networks tend to segregate as the number of courses taken increases. The next section characterizes the referrals, and we will return to the diversity implications of program selection once we propose an understanding of how referrals were made.

Figure 11: Programs sorted by fee

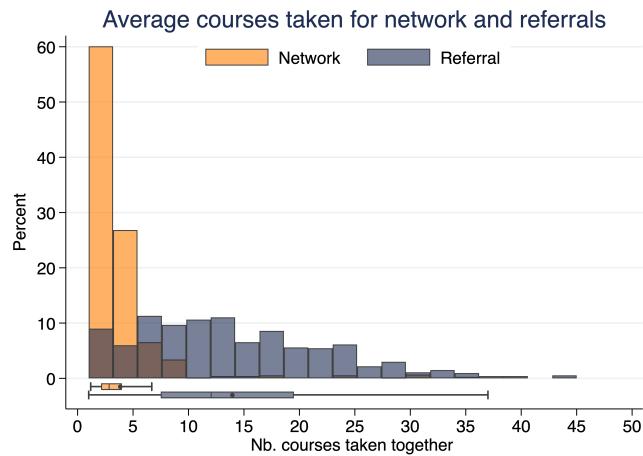

*Note:* This figure illustrates the distribution of each SES group across programs sorted by fee. the majority of low-SES select into programs with below average cost, while high-SES select into programs with above average cost. Medicine accounts for a third of all high-SES students at this university.

#### 413 5.4 Characterizing referrals 413

414 We observe 1,342 referrals from our 734 participants in our final dataset. More than 90% 414  
 415 of these consist of participants referring for both areas of the national entry exam (see 415  
 416 Appendix Table A.2). While participants made one referral for Math and Reading parts 416  
 417 of the exam, about 70% of these referrals went to two separate individuals. We compare 417  
 418 the outcomes across areas for unique referrals in Appendix Table A.3 and all referrals in 418  
 419 Appendix Table A.4. In both cases, we find no meaningful differences between referrals 419  
 420 made for Math or Reading areas of the entry exam. As referrals in both exam areas 420  
 421 come from the same referrer network, we pool referrals per participant and report their 421  
 422 averages in our main analysis to avoid inflating statistical power in our comparisons. 422  
 423 What are the characteristics of the individuals who receive referrals, and how do 423  
 424 they compare to others in the enrollment network? Because we have an entire pool of 424  
 425 potential candidates with one referral chosen from it, we compare the distributions for 425  
 426 our variables of interest between the referred and non-referred students. 426

427 First, referrals go to peers with whom the referrer has taken around 14 courses with 427  
 428 on average, compared to almost 4 on average with others in their network (see Figure 428  
 429 12). This difference of 10.1 courses is significant ( $t = 34.98, p < 0.001$ ), indicating 429  
 430 that referrers choose individuals with whom they have stronger ties. While the median 430  
 431 referral recipient has taken 12 courses together with the referrer, the median network 431  
 432 member has shared only 2.8 courses. The interquartile range for referrals spans from 7.5 432  
 433 to 19.5 courses, compared to just 2.1 to 4.0 courses for the broader network, highlighting 433  
 434 the concentration of referrals among peers with high social proximity and within same 434  
 435 program (93%). 435

Figure 12: Courses taken together with network members and referrals

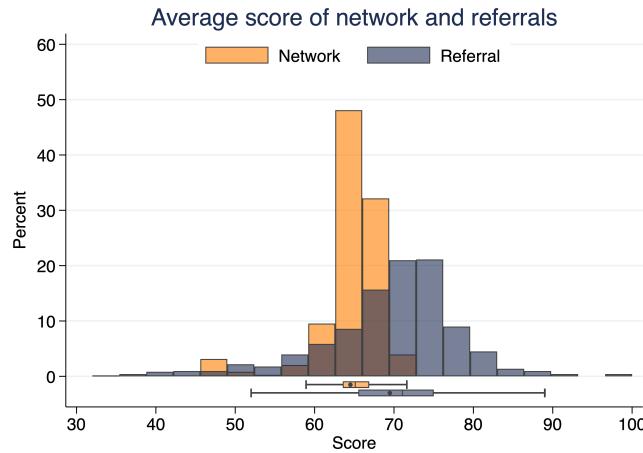

*Note:* This figure compares the distributions of the number of courses taken together between referrers and their network members (orange) versus referrers and their chosen referral recipients (dark blue) for all 734 participants. 75% of referral recipients having taken more than 7.5 courses together with the referrer, compared to only 25% of network members. The distributions are significantly different (Kolmogorov-Smirnov test  $D = 33.37, p < 0.001$ ).

436 Second, we examine entry exam score differences between referred students and the 436  
 437 broader network. Referrals go to peers with an average score of 69.5 points, compared to 437  
 438 64.5 points for other network members (see Figure 13). This difference of 5 points is sig- 438  
 439 nificant ( $t = 18.97, p < 0.001$ ), indicating that referrers choose higher-performing peers. 439

440 While the median referral recipient scores 71 points, the median network member scores 440  
 441 65.1 points. The interquartile range for referrals spans from 65.5 to 75 points, compared 441  
 442 to 63.5 to 66.9 points for the broader network, highlighting the clear concentration of 442  
 443 referrals among higher performing peers. 443

Figure 13: Entry exam scores of network members and referrals

*Note:* This figure compares the distributions of entry exam scores (Math and Reading average) between referrers' network members (orange) versus their chosen referral recipients (dark blue) for all 734 participants. 75% of referral recipients score above 65.5 points compared to only 25% of network members scoring above 66.9 points. The distributions are significantly different (Kolmogorov-Smirnov test  $D = 71.16$ ,  $p < 0.001$ ).

## 444 5.5 Effect of the Bonus treatment 444

445 Do referred individuals have different outcomes across treatments? We compare the 445  
 446 performance, number of courses taken together, and SES shares of referred individuals 446  
 447 between the **Baseline** and **Bonus** treatments in Table 3. While performance of referrals 447  
 448 across Reading, Math, and GPA are similar across treatments, middle- and high-SES 448  
 449 shares have significant differences. We find that referrals under the **Bonus** condition 449  
 450 referred a higher proportion of high-SES individuals (13.5% vs 8.8%,  $p = 0.041$ ) and 450  
 451 a lower proportion of middle-SES individuals on average (47.0% vs 53.7%,  $p = 0.072$ ). 451  
 452 However, these differences do not appear to stem from systematic behavioral changes 452

453 by any particular SES group of referrers, and the overall patterns remain largely consis- 453  
 454 tent across treatments. The similarities in academic performance and number of courses 454  
 455 taken together suggest that the core selection criteria—academic merit and social prox- 455  
 456 imity—remain unchanged between conditions. For this reason, in the remainder of the 456  
 457 paper, we report pooled results combining the averages of referral outcomes across treat- 457  
 458 ments. 458

Table 3: Characteristics of referrals by treatment condition

	<b>Baseline Referred</b>	<b>Bonus Referred</b>	<b><i>p</i></b>
Reading score	67.806	67.210	0.308
Math score	70.784	70.155	0.406
GPA	4.155	4.149	0.799
Courses taken	13.840	14.065	0.723
Low-SES	0.376	0.395	0.593
Middle-SES	0.537	0.470	0.072
High-SES	0.088	0.135	0.041
Observations	382	352	

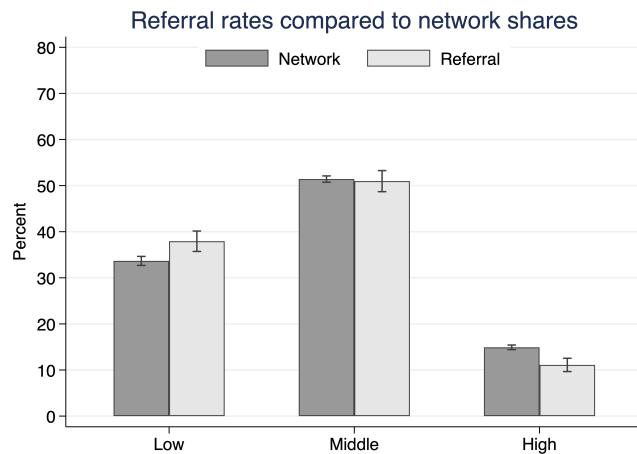

*Note:* This table compares the characteristics of network members who were referred under baseline vs bonus treatment conditions. *p*-values for binary outcomes are from two-sample tests of proportions; for continuous variables, from two-sample *t*-tests with unequal variances. All reported *p*-values are two-tailed. Reading and math scores are raw test scores out of 100. GPA is grade point average out of 5. Courses taken is the number of courses participant has taken with their referral. Low-SES, Med-SES, and High-SES are binary variables indicating the share of participants in estrato 1-2, 3-4, or 5-6, respectively. Both columns include only network members who were actually nominated for referral in each treatment condition.

## 459 5.6 Referral SES composition 459

460 We first examine the overall SES compositions in referral selection. Referrals to low- 460  
 461 SES peers constitute 37.9% of all referrals, compared to 33.7% low-SES representation 461  
 462 in individual networks (see Figure 14). This represents a modest over-representation 462

463 of 4.3 percentage points. For middle-SES students, referrals constitute 51.0% versus 463  
 464 51.4% network representation, showing virtually no difference (-0.5 pp.). High-SES 464  
 465 referrals account for 11.1% compared to 14.9% network share, an under-representation 465  
 466 of 3.8 percentage points. While these patterns suggest some deviation from proportional 466  
 467 representation—with slight over-referral to low-SES peers and under-referral to high-SES 467  
 468 peers—the magnitudes are relatively modest. Overall, referral compositions are largely 468  
 469 balanced and closely mirror the underlying network structure, with the largest deviation 469  
 470 being less than 5 percentage points for any SES group. 470

Figure 14: Referral patterns compared to network composition

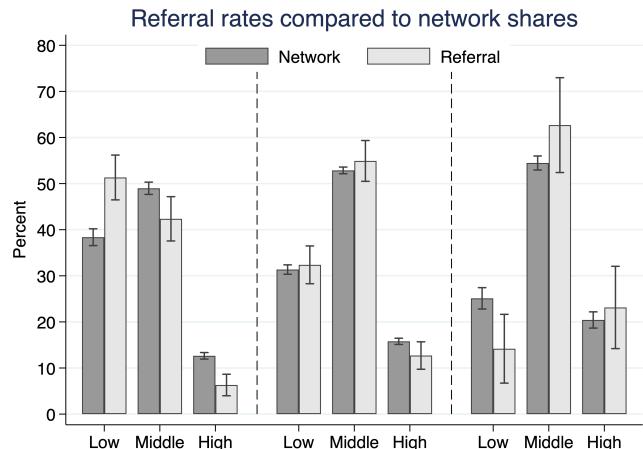

*Note:* This figure compares the average SES composition of referrers' networks (dark gray) to the SES composition of referrals (light gray). Error bars represent 95% confidence intervals.

471 Then, we examine referral patterns by referrer SES to identify potential SES biases 471  
 472 across groups. Figure 15 reveals mixed patterns of deviation from network composi- 472  
 473 tion that vary by referrer SES. Most patterns show modest deviations from network 473  
 474 composition, with differences typically ranging from 1-6 percentage points. However, at 474  
 475 the very extremes—low-SES to high-SES connections and vice versa—we observe the 475  
 476 largest discrepancies between network share (which were already biased toward same- 476  
 477 SES connections to begin with) and referral rates. Low-SES referrers show the strongest 477  
 478 same-SES preference, referring 12.9 percentage points more to low-SES students than 478

479 their network composition would suggest, while under-referring to high-SES recipients 479  
 480 by 6.3 percentage points. Conversely, high-SES referrers under-refer to low-SES students 480  
 481 by 10.9 percentage points compared to their network composition. Middle-SES referrers 481  
 482 show the most balanced patterns, with deviations generally under 3 percentage points 482  
 483 across all recipient groups. Cross-SES referral patterns, particularly between the most 483  
 484 socioeconomically distant groups, show the largest departures from network availabil- 484  
 485 ity. These results suggest that referral behavior diverges most from underlying network 485  
 486 structure when SES differences are most pronounced. 486

Figure 15: Referral patterns by referrer SES compared to network composition

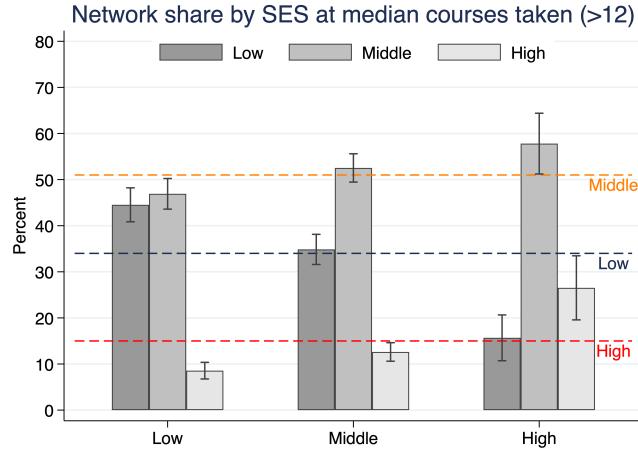

*Note:* This figure compares the average SES composition of referrers' networks (dark gray) to the SES composition of referrals (light gray) for each SES group. The panels show referral patterns for low-SES (left), middle-SES (center), and high-SES referrers (right). Error bars represent 95% confidence intervals.

## 487 5.7 Ex post referral choice sets 487

488 We now shed more light on the referral behavior after having characterized how refer- 488  
 489 rals were made. Particularly interesting is that referrals go to peers with whom the 489  
 490 median participant took 12 courses, with an average of 14. By restricting the networks 490  
 491 for courses taken above the median, we can get a snapshot of how the referral choice set 491

492 actually looked for participants before making referral decisions. As discussed in Section 492  
493 5.2, taking more courses with network members increases the share of same-SES individ- 493  
494 uals for both low- and high-SES students, and we had explored program selection as a 494  
495 potential mechanism. In Figure 16, we show the effects of network segregation on *ex post* 495  
496 referral choice sets for each SES group. Network compositions above the median num- 496  
497 ber of courses taken reveal strong segregation effects: Low-SES networks contain 44.5% 497  
498 low-SES peers, higher than the 35% university-wide share by 9.5 percentage points. 498  
499 Conversely, high-SES students are under-represented in low-SES networks at only 8.6% 499  
500 average share, compared to the 14% population share (-5.4 pp.). At the other extreme, 500  
501 high-SES networks show the reverse pattern with average low-SES share dropping to 501  
502 just 15.7%, a 19.3 percentage point decrease relative to the university average. High- 502  
503 SES students have a same-SES concentration at 26.5%, doubling their 14% population 503  
504 share (+12.5 pp.). Middle-SES networks remain relatively balanced and closely track 504  
505 population proportions across all SES groups. Taken together, these suggest observed 505  
506 referral rates of SES groups may follow the network compositions above median number 506  
507 of courses taken together. We will test this formally by setting up a choice model where 507  
508 we can take into account individual differences in network compositions across SES, and 508  
509 try to identify SES biases that go beyond SES groups' availability in the choice sets. 509

Figure 16: Network size and courses taken together by courses taken

*Note:* This figure compares the network shares of SES groups in the networks of low-, middle-, and high-SES participants above the median number of courses taken together with peers. Horizontal lines plot the university-wide shares of each SES group (Low: 35%, Mid: 51%, High: 14%). Low- and high-SES networks both become same-SES dominated at the expense of each other while middle-SES networks remain balanced. Error bars represent 95% confidence intervals.

## 5.8 Identifying the SES bias in referrals

To formally test for SES bias beyond network composition, we employ a choice modeling approach. We model a single referral outcome from mutually exclusive candidates, where our dependent variable outcome is multinomial distributed. Our design leverages the enrollment network to generate a dataset which includes alternative-specific variables for each referral decision, i.e., SES, courses taken together with the participant making the referral, as well as entry exam scores for not just the chosen alternative but all referral candidates. Using a conditional logit model on these data, we can identify whether an SES group has an aggregate bias controlling for each individual's unique enrollment network composition.

We follow an additive random utility model framework where individual  $i$  and alternative  $j$  have utility  $U_{ij}$  that is the sum of a deterministic component,  $V_{ij}$ , that depends on regressors and unknown parameters, and an unobserved random component  $\varepsilon_{ij}$ :

523        We observe the outcome  $y_i = j$  if alternative  $j$  has the highest utility of the alterna- 523  
524        tives. The probability that the outcome for individual  $i$  is alternative  $j$ , conditional on 524  
525        the regressors, is: 525

$$p_{ij} = \Pr(y_i = j) = \Pr(U_{ij} \geq U_{ik}), \quad \text{for all } k \quad (1)$$

526        The conditional logit model specifies that the probability of individual  $i$  choosing 526  
527        alternative  $j$  from choice set  $C_i$  is given by: 527

$$p_{ij} = \frac{\exp(x'_{ij}\beta)}{\sum_{l \in C_i} \exp(x'_{il}\beta)}, \quad j \in C_i \quad (2)$$

528        where  $x_{ij}$  are alternative-specific regressors, i.e., characteristics of potential referral 528  
529        candidates that vary across alternatives. In our context, individual  $i$  chooses to refer 529  
530        candidate  $j$  from their enrollment network  $C_i$ . The alternative-specific regressors include 530  
531        SES and entry exam scores of the referral candidate, and the number of courses taken 531  
532        together with the participant making the referral. Conditional logit structure eliminates 532  
533        participant-specific factors that might influence both network formation and referral 533  
534        decisions, allowing us to identify preferences within each participant's realized network. 534

535        For causal identification of SES bias, we require two identifying assumptions. Specif- 535  
536        ically: 536

- 537        1. **Conditional exogeneity.** SES and the number of courses taken together could 537  
538        be endogenous due to program selection. High-SES students sort into expensive 538  
539        programs while low-SES students choose affordable programs, creating systematic 539  
540        SES variation across enrollment networks. Similarly, the number of courses taken 540  
541        together reflects program selection decisions that may correlate with unobserved 541  
542        referral preferences. However, conditional on the realized enrollment network, the 542  
543        remaining variation in both SES and the number of courses taken together across 543  
544        referral candidates must be independent of unobserved factors affecting referral 544  
545        decisions. In the robustness checks, we show that being in the same program 545

546 with the referrer does not impact our SES bias estimates, although it reduces the 546  
547 coefficient on the number of courses taken together. 547

548 **2. Complete choice sets and independence of irrelevant alternatives.** Ad- 548  
549 ministrative data captures the complete enrollment network, with all peers who 549  
550 took at least one course with individual  $i$  and represent the true choice set for re- 550  
551 ferral decisions (unless participants have potential referral candidates with whom 551  
552 they never took classes). The independence of irrelevant alternatives (IIA) as- 552  
553 sumption requires that choices between any two alternatives be independent of 553  
554 other options in the choice set, which could be problematic if, e.g., peers within 554  
555 the same SES group are viewed as close substitutes. This concern does not apply 555  
556 to our setting because the design of our experiment ensures that choice sets are 556  
557 fixed by enrollment rather than arbitrary inclusion/exclusion of alternatives that 557  
558 create IIA violations. 558

559 Under these assumptions, the conditional logit framework controls for individual het- 559  
560 erogeneity in program selection (absorbed by conditioning on choice sets), selection into 560  
561 programs based on observable characteristics (through alternative-specific variables), and 561  
562 choice set composition effects (through the multinomial structure). Therefore,  $\beta$  should 562  
563 identify the causal effect of referral candidate SES on referral probability, holding con- 563  
564 stant the number of courses taken together and the entry exam scores of candidates. A 564  
565 significant coefficient will then indicate taste-based discrimination. 565

566 We pool participants by their SES group, and estimate the above described con- 566  
567 ditional fixed effects logit model once for low-, middle-, and high-SES referrers. We 567  
568 standardize entry exam scores and the number of courses taken together at the individ- 568  
569 ual network level. For each referrer's network, we first calculate the mean and standard 569  
570 deviation for both measures. We then compute the average of these means and standard 570  
571 deviations across all 734 referrers. Each referral candidate's entry exam score and the 571  
572 number of courses they have taken with the referrer is standardized using these network- 572  
573 level statistics. The standardization formula is  $z_i = (x - \bar{X}_i)/\sigma_i$ , where  $\bar{X}_i$  and  $\sigma_i$  are 573

574 the average of network means and standard deviations for  $C_i$ . 574

575 We now present our empirical findings and describe our first set of findings in Table 4. 575  
576 To begin with, the variance explained by all three models are extremely low, suggesting 576  
577 the role of potential SES biases in referrals that go beyond the network structure must 577  
578 be limited. Regardless, controlling for network composition, low-SES participants are 578  
579 more likely to refer other low-SES, and are less likely to refer high-SES relative to the 579  
580 probability of referring middle-SES peers. In contrast, we find that high-SES participants 580  
581 are less likely to refer other low-SES, relative to the probability of referring middle-SES 581  
582 peers. 582

Table 4: SES bias in referral decisions by referrer SES group

	Referrer SES		
	Low	Middle	High
	(1)	(2)	(3)
Low-SES candidate	0.453*** (0.109)	-0.019 (0.098)	-0.710** (0.333)
High-SES candidate	-0.584*** (0.211)	-0.255* (0.145)	0.001 (0.261)
$\chi^2$	33.47	3.18	4.94
Observations	110,142	127,088	19,767
Individuals	301	366	67

*Note:* Individual-level clustered standard errors in parentheses. \*  $p < 0.1$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$ . Each column represents a separate conditional logit regression estimated on the subsample of referrers from the indicated SES group. Coefficients represent log-odds of referring candidates from the specified SES group relative to referring middle-SES candidates. All models include individual fixed effects that control for each referrer's choice set composition.

583 Next, we include social proximity controls in our analysis. We proceed by adding 583  
584 the standardized number of courses taken together as a control in our specification and 584

585 describe the results in Table 5. A one standard deviation increase in the number of 585  
586 courses taken together proves to be highly significant across all models, with coefficients 586  
587 ranging from 0.856 to 1.049, indicating that stronger social connections substantially 587  
588 increase the probability of referral. The high  $\chi^2$  statistics suggest that these models 588  
589 explain considerably more variance than specifications without this control, highlighting 589  
590 the importance of courses taken together in referral decisions. Nevertheless, low-SES 590  
591 participants still show a strong same-SES bias relative to referring middle-SES peers 591  
592 at the average number of courses taken together. This same-SES bias is not observed 592  
593 among middle-SES or high-SES referrers, who also display no statistically significant 593  
594 bias toward low-SES candidates. No referrer group shows a positive bias for high-SES 594  
595 candidates relative to middle-SES candidates. 595

Table 5: SES bias in referral decisions by referrer SES group

	Referrer SES		
	Low	Middle	High
	(1)	(2)	(3)
Low-SES candidate	0.348*** (0.123)	-0.064 (0.115)	-0.489 (0.337)
High-SES candidate	-0.366 (0.223)	-0.165 (0.157)	-0.140 (0.286)
Courses taken (z-score)	0.856*** (0.035)	0.931*** (0.037)	1.049*** (0.126)
$\chi^2$	626.15	636.10	71.43
Observations	110,142	127,088	19,767
Individuals	301	366	67

*Note:* Individual-level clustered standard errors in parentheses. \*  $p < 0.1$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$ . Each column represents a separate conditional logit regression estimated on the subsample of referrers from the indicated SES group. Coefficients represent log-odds of referring candidates from the specified SES group relative to referring middle-SES candidates. All models include individual fixed effects that control for each referrer's choice set composition.

596 We add standardized entry exam scores (Math and Reading average) as a second 596  
 597 control variable and describe our results in Table 6. A one standard deviation increase 597  
 598 in the entry exam score proves highly significant across all models, with coefficients 598  
 599 ranging from 0.587 to 0.883. This shows merit-based considerations due to the incentive 599  
 600 structure of the experiment remained central to referral decisions. The slightly higher  $\chi^2$  600  
 601 statistics compared to the earlier specification suggests that entry exam scores improve 601  
 602 model fit. The inclusion of standardized entry exam scores strengthens SES biases. Low- 602  
 603 SES referrers maintain their same-SES bias, with now a significant negative bias against 603  
 604 high-SES. Middle-SES referrers, previously showing no SES bias, now show marginal 604

605 negative bias against high-SES. Finally, high-SES referrers exhibit marginal negative 605  
606 bias against low-SES candidates. 606

607 The evidence of a bias becoming significant when controlling for entry exam scores 607  
608 has a nuanced interpretation. While at the university-level, low-SES typically score 608  
609 lower in the entry exam, low-SES students appearing in high-SES networks are posi- 609  
610 tively selected, scoring about 0.14 standard deviations higher than middle-SES students 610  
611 (see Appendix Table A.5). Controlling for performance thus removes this positive se- 611  
612 lection and reveals the “pure” SES bias that was previously underestimated by above 612  
613 average performance of low-SES. Vice versa, high-SES in low-SES networks perform 613  
614 0.12 standard deviations better than middle-SES students. The same bias was underes- 614  
615 timated as high-SES candidates’ better performance relative to middle-SES in the same 615  
616 networks provided a meritocratic justification for getting more referrals. Controlling for 616  
617 exam scores reveal that both high- and low-SES referrers have negative SES bias towards 617  
618 one another that operates independently of - and counter to - performance-based con- 618  
619 siderations. What makes interpretation difficult is that while biased against low-SES, 619  
620 high-SES referrers do not under any specification display a positive bias towards their 620  
621 in-group. For this final reason, we do not dig any further in this direction. 621

622 To conclude, we conduct joint significance tests, testing whether low- and high-SES 622  
623 regression coefficients are jointly different from middle-SES for each regression specifi- 623  
624 cation. For low-SES referrers, the joint test remains highly significant across all three 624  
625 specifications ( $\chi^2 = 10.20, p = 0.006$  in the final model), indicating persistent SES bias 625  
626 across all specifications. In contrast, middle-SES referrers display no significant joint 626  
627 SES bias in any specification, with the test becoming increasingly non-significant as 627  
628 controls are added ( $\chi^2 = 4.13, p = 0.127$  in the final model). High-SES referrers simi- 628  
629 larly show no significant joint SES bias across all three models ( $\chi^2 = 4.28, p = 0.118$  in 629  
630 the final model). These results suggest that SES bias in referrals is primarily driven by 630  
631 low-SES. There is no sufficient evidence to conclude that middle- and high-SES referrers 631  
632 systematically discriminate against other-SES peers once we take into account the large 632  
633 differences in their network compositions due to program selection. 633

Table 6: SES bias in referral decisions by referrer SES group with academic performance controls

	Referrer SES		
	Low	Middle	High
	(1)	(2)	(3)
Low-SES candidate	0.242** (0.123)	-0.159 (0.114)	-0.600* (0.327)
High-SES candidate	-0.445** (0.222)	-0.274* (0.157)	-0.345 (0.287)
Courses taken (z-score)	0.859*** (0.036)	0.948*** (0.038)	1.043*** (0.118)
Entry exam (candidate z-score)	0.607*** (0.052)	0.587*** (0.047)	0.883*** (0.111)
$\chi^2$	789.87	756.06	120.54
Observations	110,142	127,088	19,767
Individuals	301	366	67

*Note:* Individual-level clustered standard errors in parentheses. \*  $p < 0.1$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$ . Each column represents a separate conditional logit regression estimated on the subsample of referrers from the indicated SES group. Coefficients represent log-odds of referring candidates from the specified SES group relative to referring middle-SES candidates. All models include individual fixed effects that control for each referrer's choice set composition.

- 634 **6 Robustness check** 634
- 635 Does the number of courses taken together have an independent effect that goes beyond 635  
 636 identifying peers in the same academic program? To evaluate this question we leverage 636  
 637 our administrative data, and identify peers within the same program: In each individ- 637  
 638 ual network we observe the participant-specific academic program for the participant 638

639 making the referral and alternative-specific academic program for each referral candi- 639  
640 date. We add this new variable in our specification and describe our findings in Table 640  
641 7. Being in the same academic program has a substantial positive effect on referral 641  
642 likelihood, with coefficients ranging from 1.257 to 2.198 across all referrer SES groups. 642  
643 This confirms that program affiliation serves as a strong predictor of referral decisions, 643  
644 reflecting increased familiarity. Our comparison of interest is the point estimate for the 644  
645 standardized number of courses taken. Across all three referrer groups, the standardized 645  
646 number of courses taken together maintains its statistical significance after controlling 646  
647 for same program membership. The coefficient magnitudes are expectedly smaller com- 647  
648 pared to specifications without program controls (ranging from 0.688 to 0.930) as the 648  
649 newly added variable is a moderator: Matching academic programs leads to taking more 649  
650 courses together. The remaining estimates in our model remain robust to the inclusion of 650  
651 the same-program variable with little change in point estimates. The persistence of sta- 651  
652 tistical significance (all  $p < 0.001$ ) suggests that the number of courses taken together 652  
653 has an independent effect on referral decisions. To sum, our measure of tie strength 653  
654 seems to capture meaningful social interaction patterns that lead to referrals, and go 654  
655 beyond simply identifying matching academic programs. 655

Table 7: SES bias in referral decisions by referrer SES group with program controls

	Referrer SES		
	Low	Middle	High
	(1)	(2)	(3)
Low-SES candidate	0.236** (0.119)	-0.140 (0.111)	-0.567* (0.331)
High-SES candidate	-0.421* (0.220)	-0.249 (0.158)	-0.383 (0.281)
Entry exam (candidate z-score)	0.623*** (0.054)	0.590*** (0.048)	0.892*** (0.114)
Courses taken (z-score)	0.688*** (0.032)	0.760*** (0.035)	0.930*** (0.119)
Same program	2.074*** (0.215)	2.198*** (0.185)	1.257*** (0.467)
$\chi^2$	865.35	981.99	135.47
Observations	110,142	127,088	19,767
Individuals	301	366	67

*Note:* Individual-level clustered standard errors in parentheses. \*  $p < 0.1$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$ . Each column represents a separate conditional logit regression estimated on the subsample of referrers from the indicated SES group. Coefficients represent log-odds of referring candidates from the specified SES group relative to referring middle-SES candidates. All models include individual fixed effects that control for each referrer's choice set composition.

656    **7 Conclusion**

656

657    In this paper, we study whether SES groups are biased toward one another beyond 657  
658    what is attributable to differences in their networks, and the effects of different incentive 658  
659    structures on referral behavior. Through a lab-in-the-field experiment that leverages 659  
660    enrollment networks at a socially diverse university, we find that the SES biases in 660  
661    referrals originate mostly from network structures, and referrals under performance-pay 661  
662    incentives do not exacerbate existing SES inequalities. 662

663    Our findings reveal that enrollment networks are surprisingly segregated and referrals 663  
664    from these networks reflect closely the choice sets of the referrers. We identify program 664  
665    selection as the key mechanism driving this segregation. Low-SES students select into 665  
666    more affordable programs, and program selection plays a major part in segregating 666  
667    SES groups where low- and high-SES take more courses with their own SES group. 667  
668    Consequently, referrals come almost exclusively from the same academic program as the 668  
669    referrer, limiting the SES-diversity of their choice sets. Regardless of the bonus for the 669  
670    referral candidate, participants also pick higher performing peers with whom they have 670  
671    taken many courses together. We find that only low-SES referrers exhibit a same-SES 671  
672    bias. These findings suggest that the underlying network structure plays a crucial role 672  
673    in referrals, where institutional action can remedy the network segregation. 673

674    These results complement the broader literature where much of the bias in referrals 674  
675    can be attributable to the “practical” choice sets of the referrers. While previous work 675  
676    demonstrates that about half of referrals come from a smaller, elicited network of close 676  
677    friends ([Hederos et al., 2025](#)), we go the other way and use administrative data to 677  
678    construct a complete network which presumably includes close social relationships at the 678  
679    institutional level. Having access to the complete network thus eliminates any potential 679  
680    for under or overestimating taste-based biases ([Griffith, 2022](#)). Under performance-pay 680  
681    incentives, referrers identify productive others regardless of additional financial rewards 681  
682    for the referral candidate. Still, the lack of a treatment effect suggests that in both 682  
683    incentive structures referrers pick close ties, shifting the responsibility to institutional 683

684 actors to create diverse environments where cross-SES social interaction can take place 684  
685 more frequently and allow more diversity in networks. 685

686 These findings have policy implications. Looking forward, institutions can play a 686  
687 crucial role in achieving SES equality of opportunity in higher education. Universities 687  
688 are already a setting in which low-SES get exposed to typically a higher than popula- 688  
689 tion share of higher-SES individuals than at other settings (Chetty et al., 2022a). Yet, 689  
690 segregation within the higher education institutions remain a source for SES inequal- 690  
691 ity. If low-SES peers never get to interact in meaningful ways with higher-SES, e.g., by 691  
692 taking courses together, the premise of social mobility through social channels remains 692  
693 severely underexploited. Future studies should work on ways to reduce SES segregation 693  
694 in collaboration with institutions, where having access to complete enrollment networks 694  
695 in addition to the typical friendship elicitation methods could help identifying the exact 695  
696 overlap between the two distinct approaches. 696

823 **A Additional Figures and Tables**

823

824 **Additional Figures**

824

Table A.1: Selection into the experiment

	<b>University</b>	<b>Sample</b>	<b>p</b>
Reading score	62.651	65.183	0.000
Math score	63.973	67.477	0.000
GPA	3.958	4.012	0.000
Low-SES	0.343	0.410	0.000
Middle-SES	0.505	0.499	0.763
High-SES	0.153	0.091	0.000
Female	0.567	0.530	0.060
Age	21.154	20.651	0.000
Observations	4,417	734	

*Note:* This table compares characteristics between the university and the experimental sample. *p*-values for binary outcomes (Low-SES, Med-SES, High-SES, Female) are from two-sample tests of proportions; for continuous variables, from two-sample *t*-tests with unequal variances. All reported *p*-values are two-tailed.

Table A.2: Distribution of referrals by area

<b>Area</b>	<b>Only one area</b>	<b>Both areas</b>	<b>Total</b>
Verbal	65	608	673
Math	61	608	669
Total	126	1,216	1,342

*Note:* The table shows how many referrers made referrals in only one area versus both areas. “Only one area” indicates individuals who made referrals exclusively for one area of the exam. “Both areas” shows individuals who made referrals in both verbal and math areas. The majority of referrers (608) made referrals in both areas.

Table A.3: Referral characteristics by exam area (unique referrals only)

	<b>Reading</b>	<b>Math</b>	<b><i>p</i></b>
Reading score	67.733	67.126	0.252
Math score	69.339	71.151	0.008
GPA	4.136	4.136	0.987
Courses taken	13.916	13.019	0.123
Low-SES	0.372	0.385	0.666
Med-SES	0.526	0.518	0.801
High-SES	0.103	0.097	0.781
Observations	487	483	

*Note:* This table compares characteristics of uniquely referred students by entry exam area for the referral (verbal vs. math). *p*-values are from two-sample t-tests with unequal variances. Referrals in Math area go to peers with significantly higher math scores ( $p = 0.008$ ), while we find no significant differences for Reading scores, GPA, courses taken, or SES composition for referrals across the two areas. Excluding referrals going to the same individuals does not change the outcomes for referrals compared to Appendix Table A.4

Table A.4: Referral characteristics by academic area

	<b>Reading</b>	<b>Math</b>	<b>p</b>
Reading score	67.85	67.41	0.348
Math score	70.04	71.36	0.029
GPA	4.153	4.153	0.984
Courses taken	14.467	13.822	0.206
Low-SES	37%	38%	0.714
Middle-SES	51%	51%	0.829
High-SES	11%	11%	0.824
Observations	673	669	

*Note:* This table compares characteristics of referred students by entry exam area for the referral (verbal vs. math). *p*-values are from two-sample t-tests with unequal variances. Referrals in Math area go to peers with significantly higher math scores ( $p = 0.029$ ), while we find no significant differences for Reading scores, GPA, courses taken, or SES composition for referrals across the two areas.

Table A.5: Average entry exam z-scores by SES network connections

<b>Referrer SES</b>	<b>Network average for SES group</b>		
	<b>Low</b>	<b>Middle</b>	<b>High</b>
Low	0.086	-0.018	0.144
Middle	0.186	0.023	0.215
High	0.204	0.064	0.285
All	-0.361	-0.078	0.169

*Note:* This table shows average (Math and Reading) standardized entry exam scores for individuals of different SES levels (rows) when connected to peers of specific SES levels (columns). The “All” row shows the overall average scores across all participant SES levels when connected to each network SES type. Higher values indicate better academic performance in SD’s.

826 **B Experiment**

826

827 We include the English version of the instructions used in Qualtrics. Participants saw 827  
828 the Spanish version. Horizontal lines in the text indicate page breaks and clarifying 828  
829 comments are inside brackets. 829

830 **Consent**

830

831 You have been invited to participate in this decision-making study. This study is directed 831  
832 by [omitted for anonymous review] and organized with the support of the Social Bee Lab 832  
833 (Social Behavior and Experimental Economics Laboratory) at UNAB. 833

834 In this study, we will pay **one (1)** out of every **ten (10)** participants, who will be 834  
835 randomly selected. Each selected person will receive a fixed payment of **70,000** (seventy 835  
836 thousand pesos) for completing the study. Additionally, they can earn up to **270,000** 836  
837 (two hundred and seventy thousand pesos), depending on their decisions. So, in total, 837  
838 if you are selected to receive payment, you can earn up to **340,000** (three hundred and 838  
839 forty thousand pesos) for completing this study. 839

840 If you are selected, you can claim your payment at any Banco de Bogotá office by 840  
841 presenting your ID. Your participation in this study is voluntary and you can leave the 841  
842 study at any time. If you withdraw before completing the study, you will not receive 842  
843 any payment. 843

844 The estimated duration of this study is 20 minutes. 844

845 The purpose of this study is to understand how people make decisions. For this, we will 845  
846 use administrative information from the university such as the SABER 11 test scores of 846  
847 various students (including you). Your responses will not be shared with anyone and your 847  
848 participation will not affect your academic records. To maintain strict confidentiality, the 848  
849 research results will not be associated at any time with information that could personally 849

850 identify you. 850

851 There are no risks associated with your participation in this study beyond everyday risks. 851  
852 However, if you wish to report any problems, you can contact Professor [omitted for 852  
853 anonymous review]. For questions related to your rights as a research study participant, 853  
854 you can contact the IRB office of [omitted for anonymous review]. 854

855 By selecting the option “I want to participate in the study” below, you give your con- 855  
856 sent to participate in this study and allow us to compare your responses with some 856  
857 administrative records from the university. 857

858 • I want to participate in the study [advances to next page] 858

859 • I do not want to participate in the study 859

860 ————— 860

## 861 **Student Information** 861

862 Please write your student code. In case you are enrolled in more than one program 862  
863 simultaneously, write the code of the first program you entered: 863

864 [Student ID code] 864

865 What semester are you currently in? 865

866 [Slider ranging from 1 to 11] 866

867 ————— 867

868 [Random assignment to treatment or control] 868

869 **Instructions**

869

870 The instructions for this study are presented in the following video. Please watch it 870  
871 carefully. We will explain your participation and how earnings are determined if you are 871  
872 selected to receive payment. 872

873 [Treatment-specific instructions in video format] 873

874 If you want to read the text of the instructions narrated in the video, press the “Read 874  
875 instruction text” button. Also know that in each question, there will be a button with 875  
876 information that will remind you if that question has earnings and how it is calculated, 876  
877 in case you have any doubts. 877

878 • I want to read the instructions text [text version below] 878

879 —————— 879

880 In this study, you will respond to three types of questions. First, are the belief questions. 880  
881 For belief questions, we will use as reference the results of the SABER 11 test that you 881  
882 and other students took to enter the university, focused on three areas of the exam: 882  
883 mathematics, reading, and English. 883

884 For each area, we will take the scores of all university students and order them from 884  
885 lowest to highest. We will then group them into 100 percentiles. The percentile is a 885  
886 position measure that indicates the percentage of students with an exam score that is 886  
887 above or below a value. 887

888 For example, if your score in mathematics is in the 20th percentile, it means that 20 888  
889 percent of university students have a score lower than yours and the remaining 80 percent 889  
890 have a higher score. A sample belief question is: “compared to university students, in 890  
891 what percentile is your score for mathematics?” 891

892 If your answer is correct, you can earn 20 thousand pesos. We say your answer is correct 892

893 if the difference between the percentile you suggest and the actual percentile of your 893  
894 score is not greater than 7 units. For example, if you have a score that is in the 33rd 894  
895 percentile and you say it is in the 38th, the answer is correct because the difference is 895  
896 less than 7. But if you answer that it is in the 41st, the difference is greater than 7 and 896  
897 the answer is incorrect. 897

898 The second type of questions are recommendation questions and are also based on the 898  
899 mathematics, reading, and English areas of the SABER 11 test. We will ask you to think 899  
900 about the students with whom you have taken or are taking classes, to recommend from 900  
901 among them the person you consider best at solving problems similar to those on the 901  
902 SABER 11 test. 902

903 When you start typing the name of your recommended person, the computer will show 903  
904 suggestions with the full name, program, and university entry year of different students. 904  
905 Choose the person you want to recommend. If the name doesn't appear, check that you 905  
906 are writing it correctly. Do not use accents and use 'n' instead of 'ñ'. If it still doesn't 906  
907 appear, it may be because that person is not enrolled this semester or because they did 907  
908 not take the SABER 11 test. In that case, recommend someone else. 908

909 You can earn up to 250,000 pesos for your recommendation. We will multiply your 909  
910 recommended person's score by 100 pesos if they are in the first 50 percentiles. We will 910  
911 multiply it by 500 pesos if your recommended person's score is between the 51st and 911  
912 65th percentile. If it is between the 66th and 80th percentile, we will multiply your 912  
913 recommended person's score by 1000 pesos. If the score is between the 81st and 90th 913  
914 percentile, you earn 1500 pesos multiplied by your recommended person's score. And if 914  
915 the score is between the 91st and 100th percentile, we will multiply your recommended 915  
916 person's score by 2500 pesos to determine the earnings. 916

917 The third type of questions are information questions and focus on aspects of your 917  
918 personal life or your relationship with the people you have recommended. 918

919 **Earnings**

919

920 Now we will explain who gets paid for participating and how the earnings for this study 920  
921 are assigned. The computer will randomly select one out of every 10 participants to pay 921  
922 for their responses. For selected individuals, the computer will randomly choose one of 922  
923 the three areas, and from that chosen area, it will pay for one of the belief questions. 923

924 Similarly, the computer will randomly select one of the three areas to pay for one of the 924  
925 recommendation questions. 925

926 **Additionally, if you are selected to receive payment, your recommended per- 926  
927 son in the chosen area will receive a fixed payment of 100 thousand pesos. 927  
928 [Only seen if assigned to the treatment]** 928

929 Each person selected to receive payment for this study can earn: up to 20 thousand pesos 929  
930 for one of the belief questions, up to 250 thousand pesos for one of the recommendation 930  
931 questions, and a fixed payment of 70 thousand pesos for completing the study. 931

932 Selected individuals can earn up to 340 thousand pesos. 932

---

933 \_\_\_\_\_ 933

934 [Participants go through all three Subject Areas in randomized order] 934

935 **Subject Areas**

935

936 **Critical Reading**

936

937 For this section, we will use as reference the Critical Reading test from SABER 11, which 937  
938 evaluates the necessary competencies to understand, interpret, and evaluate texts that 938  
939 can be found in everyday life and in non-specialized academic fields. 939

940 [Clicking shows the example question from SABER 11 below] 940

941 Although the democratic political tradition dates back to ancient Greece, political 941  
942 thinkers did not address the democratic cause until the 19th century. Until then, democ- 942  
943 racy had been rejected as the government of the ignorant and unenlightened masses. 943  
944 Today it seems that we have all become democrats without having solid arguments in 944  
945 favor. Liberals, conservatives, socialists, communists, anarchists, and even fascists have 945  
946 rushed to proclaim the virtues of democracy and to show their democratic credentials 946  
947 (Andrew Heywood). According to the text, which political positions identify themselves 947  
948 as democratic? 948

- 949     • Only political positions that are not extremist 949  
950     • The most recent political positions historically 950  
951     • The majority of existing political positions 951  
952     • The totality of possible political currents 952

953 ————— 953

## 954   **Mathematics** 954

955 This section references the Mathematics test from SABER 11, which evaluates people's 955  
956 competencies to face situations that can be resolved using certain mathematical tools. 956

957 [Clicking shows the example question from SABER 11 below] 957

958 A person living in Colombia has investments in dollars in the United States and knows 958  
959 that the exchange rate of the dollar against the Colombian peso will remain constant 959  
960 this month, with 1 dollar equivalent to 2,000 Colombian pesos. Their investment, in 960  
961 dollars, will yield profits of 3% in the same period. A friend assures them that their 961  
962 profits in pesos will also be 3%. Their friend's statement is: 962

- 963     • Correct. The proportion in which the investment increases in dollars is the same 963  
964         as in pesos. 964

- Incorrect. The exact value of the investment should be known. 965
  - Correct. 3% is a fixed proportion in either currency. 966
  - Incorrect. 3% is a larger increase in Colombian pesos. 967

968

## **969 English**

970 This section uses the English test from SABER 11 as a reference, which evaluates that 970  
971 the person demonstrates their communicative abilities in reading and language use in 971  
972 this language. 972

973 [Clicking shows the example question from SABER 11 below] 973

974 Complete the conversations by marking the correct option.

- Conversation 1: I can't eat a cold sandwich. It is horrible!

— I hope so.

— I agree.

— I am not.

  - Conversation 2: It rained a lot last night!

— Did you accept?

— Did you understand?

984 [Following parts are identical for all Subject Areas and are not repeated here for brevity] 984

985    **Your Score**

985

986    Compared to university students, in which percentile do you think your [Subject Area] 986  
987    test score falls (1 is the lowest percentile and 100 the highest)? 987

988    [Clicking shows the explanations below] 988

989    How is a percentile calculated? 989

990    A percentile is a position measurement. To calculate it, we take the test scores for all 990  
991    students currently enrolled in the university and order them from lowest to highest. The 991  
992    percentile value you choose refers to the percentage of students whose score is below 992  
993    yours. For example, if you choose the 20th percentile, you're indicating that 20% of 993  
994    students have a score lower than yours and the remaining 80% have a score higher than 994  
995    yours. 995

996    What can I earn for this question? 996

997    For your answer, you can earn **20,000 (twenty thousand) PESOS**, but only if the 997  
998    difference between your response and the correct percentile is less than 7. For example, if 998  
999    the percentile where your score falls is 33 and you respond with 38 (or 28), the difference 999  
1000    is 5 and the answer is considered correct. But if you respond with 41 or more (or 25 or 1000  
1001    less), for example, the difference would be greater than 7 and the answer is incorrect. 1001

1002    Please move the sphere to indicate which percentile you think your score falls in: 1002

1003    [Slider with values from 0 to 100] 1003

1004    

---

 1004

1005 **Recommendation**

1005

1006 Among the people with whom you have taken any class at the university, who is your 1006  
1007 recommendation for the [Subject Area] test? Please write that person's name in the 1007  
1008 box below: 1008

1009 **Important:** You will not be considered for payment unless the recommended 1009  
1010 person is someone with whom you have taken at least one class during your 1010  
1011 studies. 1011

1012 Your response is only a recommendation for the purposes of this study and we will **not** 1012  
1013 contact your recommended person at any time. 1013

1014 [Clicking shows the explanations below] 1014

1015 Who can I recommend? 1015

1016 Your recommendation **must** be someone with whom you have taken (or are taking) a 1016  
1017 class. If not, your answer will not be considered for payment. The person you recommend 1017  
1018 will not be contacted or receive any benefit from your recommendation. 1018

1019 As you write, you will see up to 7 suggested student names containing the letters you 1019  
1020 have entered. The more you write, the more accurate the suggestions will be. Please 1020  
1021 write **without** accents and use the letter 'n' instead of 'ñ'. If the name of the person 1021  
1022 you're writing doesn't appear, it could be because you made an error while writing the 1022  
1023 name. 1023

1024 If the name is correct and still doesn't appear, it could be because the student is not en- 1024  
1025 rolled this semester or didn't take the SABER 11 test. In that case, you must recommend 1025  
1026 someone else. 1026

1027 My earnings for this question? 1027

1028 For your recommendation, you could receive earnings of up to 250,000 (two hundred and 1028  
1029 fifty thousand) PESOS. The earnings are calculated based on your recommendation's 1029  
1030 score and the percentile of that score compared to other UNAB students, as follows: 1030

- 1031 • We will multiply your recommendation's score by \$100 (one hundred) pesos if it's 1031  
1032 between the 1st and 50th percentiles 1032
- 1033 • We will multiply your recommendation's score by \$500 (five hundred) pesos if it's 1033  
1034 between the 51st and 65th percentiles 1034
- 1035 • We will multiply your recommendation's score by \$1000 (one thousand) pesos if 1035  
1036 it's between the 66th and 80th percentiles 1036
- 1037 • We will multiply your recommendation's score by \$1500 (one thousand five hun- 1037  
1038 dred) pesos if it's between the 81st and 90th percentiles 1038
- 1039 • We will multiply your recommendation's score by \$2500 (two thousand five hun- 1039  
1040 dred) pesos if it's between the 91st and 100th percentiles 1040

1041 This is illustrated in the image below: 1041

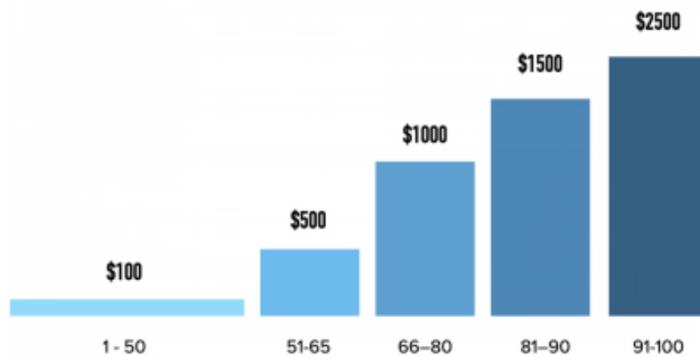

Figure B.1: Earnings for recommendation questions

1042 For example, if your recommendation got 54 points and the score is in the 48th percentile, 1042

1043 you could earn  $54 \times 100 = 5400$  PESOS. But, if the same score of 54 points were in the 1043  
1044 98th percentile, you could earn  $54 \times 2500 = 135,000$  PESOS. 1044

1045 [Text field with student name suggestions popping up as participant types] 1045

1046 \_\_\_\_\_ 1046

## 1047 Relationship with your recommendation 1047

1048 How close is your relationship with your recommendedation: “[Name of the student 1048  
1049 selected from earlier]”? (0 indicates you are barely acquaintances and 10 means you are 1049  
1050 very close) 1050

1051 [Slider with values from 0 to 10] 1051

1052 \_\_\_\_\_ 1052

## 1053 Your recommendation's score 1053

1054 Compared to university students, in which percentile do you think [Name of the student 1054  
1055 selected from earlier]’s score falls in the [Subject Area] test (1 is the lowest percentile 1055  
1056 and 100 the highest)? 1056

1057 [Clicking shows the explanations below] 1057

1058 How is a percentile calculated? 1058

1059 A percentile is a position measurement. To calculate it, we take the test scores for all 1059  
1060 students currently enrolled in the university and order them from lowest to highest. The 1060  
1061 percentile value you choose refers to the percentage of students whose score is below 1061  
1062 yours. For example, if you choose the 20th percentile, you’re indicating that 20% of 1062  
1063 students have a score lower than yours and the remaining 80% have a score higher than 1063  
1064 yours. 1064

1065 What can I earn for this question?

1065

1066 For your answer, you can earn **20,000 (twenty thousand) PESOS**, but only if the 1066  
1067 difference between your response and the correct percentile is less than 7. For example, 1067  
1068 if the percentile where your recommended person's score falls is 33 and you respond with 1068  
1069 38 (or 28), the difference is 5 and the answer is considered correct. But if you respond 1069  
1070 with 41 or more (or 25 or less), for example, the difference would be greater than 7 and 1070  
1071 the answer is incorrect.

1071

1072 Please move the sphere to indicate which percentile you think your recommended per- 1072  
1073 son's score falls in:

1073

1075

## 1076 Demographic Information

1076

1077 What is the highest level of education achieved by your father?

1077

1078 [Primary, High School, University, Graduate Studies, Not Applicable]

1078

1079 What is the highest level of education achieved by your mother?

1079

1080 [Primary, High School, University, Graduate Studies, Not Applicable]

1080

1081 Please indicate the socio-economic group to which your family belongs:

1081

1082 [Group A (Strata 1 or 2), Group B (Strata 3 or 4), Group C (Strata 5 or 6)]

1082

1083

1083

## 1084 UNAB Students Distribution

1085 Thinking about UNAB students, in your opinion, what percentage belongs to each socio- 1085  
1086 economic group? The total must sum to 100%: 1086

1087 [Group A (Strata 1 or 2) percentage input area] 1087  
1088 [Group B (Strata 3 or 4) percentage input area] 1088  
1089 [Group C (Strata 5 or 6) percentage input area] 1089  
1090 [Shows sum of above percentages] 1090

---

## 1092 End of the Experiment

1093 Thank you for participating in this study. 1093

1094 If you are chosen to receive payment for your participation, you will receive a confirma- 1094  
1095 tion to your UNAB email and a link to fill out a form with your information. The process 1095  
1096 of processing payments is done through Nequi and takes approximately 15 business days, 1096  
1097 counted from the day of your participation. 1097

1098 [Clicking shows the explanations below] 1098

1099 Who gets paid and how is it decided? 1099

1100 The computer will randomly select one out of every ten participants in this study to be 1100  
1101 paid for their decisions. 1101

1102 For selected individuals, the computer will randomly select one area: mathematics, 1102  
1103 reading, or English, and from that area will select one of the belief questions. If the 1103  
1104 answer to that question is correct, the participant will receive 20,000 pesos. 1104

1105 The computer will randomly select an area (mathematics, critical reading, or English) to 1105  
1106 pay for one of the recommendation questions. The area chosen for the recommendation 1106  
1107 question is independent of the area chosen for the belief question. The computer will 1107  
1108 take one of the two recommendations you have made for the chosen area. Depending on 1108  
1109 your recommendation's score, you could win up to 250,000 pesos. 1109

1110 Additionally, people selected to receive payment for their participation will have a fixed 1110  
1111 earnings of 70,000 pesos for completing the study. 1111

1112 \_\_\_\_\_ 1112

## 1113 **Participation** 1113

1114 In the future, we will conduct studies similar to this one where people can earn money 1114  
1115 for their participation. The participation in these studies is by invitation only. Please 1115  
1116 indicate if you are interested in being invited to other studies similar to this one: 1116

1117 [Yes, No] 1117
